

## The MuonDigitizer OO code

*Paul Colrain and Miriam Gandelman*

**LAPE-IF/UFRJ**

- The code runs for all Gaudi versions reading in the RawHits from a DST (using the SICb converter).
- It digitizes the hits and produce the PadHits according to a given chamber/pad configuration.
- All the geometry information is read in from a XML file (chamber dimensions, pad configuration, etc.).

## ✓ The MuonDigitizer Code

### ✗ MuonDigitizer:

- ★ create 5 Stations
- ★ configure the Stations
- ★ read in the MCHits and distribute them to the Stations
- ★ stations → digitize

### ✗ Station:

- ★ create its Chambers
- ★ set the Chambers' technology, ID, ZPosition, Inner and Outer Dimensions
- ★ distribute the MCHits for its Chambers
- ★ chambers → digitize

**✗ Chamber:**

★ **Virtual Class.** The concrete objects are CPC's, WPC's and WSC's

★ **create its Layers**

**✗ Layer:**

★ **produce layerHits (pad ID, xyz of the pad center)**

**✗ CPC,WPC or WSC:**

★ **receive the layerHits and produce the padHits (the actual digitization is done here)**

★ **if both layers are hit in the same pad, we keep one of them, otherwise, we keep both pads.**
